Abstract

Introduction

This work reflects on a possible extension to the canonical formalism of quantum mechanics. The main goal of this extension is to allow us to access a much larger class of interesting Hamiltonians which are non-Hermitian but nevertheless, physical and therefore possibly of great importance to the advancement of new and physically significant theories.

In “The principles of quantum mechanics”, Paul Dirac advises us that “it is important to remember that science is concerned only with *observable* things and that we can observe an object only by letting it interact with some outside influence”[1]. This means that in order to study valid physical systems, these systems must satisfy the fundamental postulates of quantum mechanical theory. Nearly all these postulates are based in physical properties. For example, one postulate establishes that time evolution of a quantum system must be *unitary* (i.e. probability conserving), another requires that the energy spectrum of the system is bounded below so a lowest energy state can be measured. In quantum mechanics, the Hamiltonian operator (\hat{H}) encapsulates the total energy of a system. As explained already, a system’s energy spectrum is required to be bounded and real in order to be measurable. According to the fundamental axioms, if the operator \hat{H} satisfies the mathematical property known as Hermiticity (these operators are also known as self-adjoint in mathematics), then \hat{H} will be an adequate physical observable. Interestingly, the Hermiticity postulate stands out from others in the conventional theory of quantum mechanics because it is mathematical rather than physical in its character[2]. An operator \hat{O} that is Hermitian has the property that its effect on the vectors of the Hilbert space in which \hat{O} is defined is independent of the order in which \hat{O} acts on said vectors[3]

$$\hat{O}|\psi\rangle = \langle\psi|\hat{O}^\dagger \quad (1.1)$$

Despite of the correctness of Hermiticity, since this property depends on the definition of the inner-product used, some believe that perhaps we have ended up with an overly restrictive quantum mechanical theory. The aim of this review is to summarize the present developments of a more physical alternative to Hermiticity. This postulate is referred to as space–time reflection symmetry (\mathcal{PT} symmetry)[4].

1.1 \mathcal{PT} -symmetry

In the late nineties, Carl Bender et al presented a \mathcal{PT} -symmetric theory of quantum mechanics, their aim was to explain a conjecture on the reality and positiveness of the spectrum of a non-Hermitian Hamiltonian proposed by Bessis[5]. This new \mathcal{PT} -symmetric theory can be viewed as an analytical continuation of the conventional theory from real into the complex phase space[6].

The critical question that must be answered, is whether a \mathcal{PT} -symmetric Hamiltonian defines a valid physical theory of quantum mechanics. By a physical theory we mean that the energy spectra of a system described by \hat{H} must be real and bounded below, and since the norm of a state is interpreted as a probability, this norm must be positive. Finally, we must show that the time evolution of the theory is unitary. This means that as a state vector evolves in time the state's probability does not leak away[4][2].

1.1.1 The \mathcal{PT} operator

The \mathcal{PT} operator is the anti-linear operator composed of the linear parity operator (\mathcal{P}), which performs spatial reflection, and the anti-linear time-reversal operator (\mathcal{T}). These operators act on position and momentum operators in the following form

$$\begin{aligned}\mathcal{P}: \quad \hat{x} &\rightarrow -\hat{x}, & \hat{p} &\rightarrow -\hat{p}, \\ \mathcal{T}: \quad \hat{x} &\rightarrow \hat{x}, & \hat{p} &\rightarrow -\hat{p}, \quad i \rightarrow -i.\end{aligned}\tag{1.2}$$

Some Hamiltonians may not be symmetric under \mathcal{P} or \mathcal{T} separately, but Hamiltonians that remain invariant under the influence of the \mathcal{PT} operator are labelled as \mathcal{PT} -symmetric. A Hamiltonian \hat{H} will possess unbroken \mathcal{PT} symmetry if it's eigenstates are simultaneously eigenstates of the \mathcal{PT} operator, or in other words, if \hat{H} and the \mathcal{PT} operator commute. Otherwise we say that the Hamiltonian's \mathcal{PT} -symmetry is broken[2][7][4]. If the symmetry is unbroken, then the eigenspectrum of \hat{H} is fully real and bounded below. The effectiveness of \mathcal{PT} symmetry as a tool to investigate the spectra of some non-Hermitian Hamiltonians has been proved rigorously in various works, such as Dorey et al[8], Bender and Boettcher[5], Brody[9], Bender and Mannheim [10], Bender et al[6], Mostafazadeh[11][12] amongst several others.

1.1.2 The \mathcal{CPT} inner product

To be able to describe precisely the nature of \mathcal{PT} -symmetric quantum mechanics, we must delve briefly into the inner-product under which our theory satisfies the axioms of conventional quantum mechanics. It is important to note that \mathcal{PT} -symmetric quantum mechanics is a kind of 'bootstrap' theory[2], since infinitely many inner-products exist for a given vector space, we can construct an inner product whose associated norm is positive definite by design. This inner-product is in general dependent on the characteristics of the Hamiltonian in question and it guarantees that the underlying dynamics of any \mathcal{PT} -symmetric Hamiltonian satisfies unitarity[4]. Firstly, it is necessary to solve for the eigenstates of the Hamiltonian before knowing the Hilbert space and the associated inner product. To guarantee a positive norm for our theory, we will construct a new linear operator \mathcal{C} that commutes with both \hat{H} and \mathcal{PT} , we use the symbol \mathcal{C} to represent this symmetry because it's properties are similar to those of the charge conjugation operator in particle physics[2].

The \mathcal{C} operator

When the \mathcal{PT} -symmetry of \hat{H} is unbroken, then \hat{H} and \mathcal{PT} commute. This statement is equivalent to saying that the eigenfunctions $\phi_n(x)$ of \hat{H} are simultaneously eigenstates of \mathcal{PT} [13].

$$\mathcal{PT}\phi_n(x) = \lambda_n\phi_n(x),\tag{1.3}$$

Where λ_n is a pure phase. Without loss of generality, for each n the phase can be absorbed into $\phi_n(x)$ by rescaling, this makes the eigenvalue of the \mathcal{PT} operator unity[13]:

$$\mathcal{PT}\phi_n(x) = \phi_n^*(-x) = \phi_n(x). \quad (1.4)$$

There is strong numerical evidence of the completeness of the eigenfunctions $\phi_n(x)$ [7][13][14]. In the coordinate basis, the completeness statement reads:

$$\sum_n (-1)^n \phi_n(x) \phi_n(y) = \delta(x - y), \quad x, y \in \mathbb{R} \quad (1.5)$$

the unconventional $(-1)^n$ factor in 1.5 can be explained if we define the \mathcal{PT} inner product as

$$\begin{aligned} (f, g) &= \int dx [\mathcal{PT}f(x)] g(x) \\ &= \int dx f^*(-x) g(x). \end{aligned} \quad (1.6)$$

where the integral above follows a path in the complex plane. Under this definition the eigenstate norms alternate in sign depending on the value n . This means that the metric associated with the \mathcal{PT} inner product is indefinite[13][15]. In quantum theory, the norm of states is interpreted as a probability and this means that the indefinite metric described above presents a serious problem for the validity of \mathcal{PT} -symmetric quantum theory. The solution to this problem lies in finding an interpretation for the negative valued norms[6]. The general claim presented in the literature is that for any theory with unbroken \mathcal{PT} -symmetry there exists a symmetry of the Hamiltonian that describes the negative and positive norm states. To describe this symmetry of \hat{H} it is necessary to construct a linear operator denoted by \mathcal{C} [4][7][13]. When represented in position space \mathcal{C} is a sum over the energy eigenstates of \hat{H} :

$$\mathcal{C} = \sum_n \phi_n(x) \phi_n(y) \quad (1.7)$$

From this definition, and the relation $(\phi_m(y), \phi_n(y)) = \int dy \phi_m(y) \phi_n(y)$ we can verify that the eigenvalues of \mathcal{C} are ± 1

$$\begin{aligned} \mathcal{C}\phi_n(x) &= \int dy \mathcal{C} \phi_n(y) \\ &= \sum_m \phi_m(x) \int dy \phi_m(y) \phi_n(y) \\ &= (-1)^n \phi_n(x) \end{aligned} \quad (1.8)$$

The \mathcal{PT} norms signatures can therefore be interpreted as the “charge” of the states, while \mathcal{C} is the operator used to measure this charge[13].

The \mathcal{C} operator commutes with the \mathcal{PT} operator, but it does not commute with the parity operator \mathcal{P} . Notice that \mathcal{C} and \mathcal{P} operators are square roots of $\delta(x - y)$ the unity operator[7]

$$\mathcal{P}^2 = \mathcal{C}^2 = \mathbb{1}, \quad (1.9)$$

where $\mathcal{P} \neq \mathcal{C}$, since \mathcal{P} is real and \mathcal{C} is complex valued[4][13].

Using the newly constructed \mathcal{C} operator, we can redesign the \mathcal{PT} inner product to suit the conventional probabilistic interpretation of the vector norms in quantum mechanics

$$(f, g) = \int dx [\mathcal{CPT}f(x)] g(x) \quad (1.10)$$

Time evolution

Time-evolution in conventional quantum mechanics can be described using the unitary operator $\hat{U} = e^{-i\hat{H}t/\hbar}$. \hat{U} is unitary because the Hamiltonian \hat{H} is Hermitian, that means that as the state $\psi(x)$ evolves in time, its norm remains constant in time. Hence time evolution of a state $\psi(x)$ from time $0 \rightarrow t$ is written as

$$\psi(x, t) = \hat{U}\psi(x, 0) \tag{2.1}$$

Consequences and applications

Conclusion
